If it looks like this than transforming only the explanatory variable to $\log x$ or $\frac{1}{x}$ is sufficient.		Here, either we can transform: <ul style="list-style-type: none">y to $\log y$ or $\frac{1}{y}$ orx to $\log x$ or $\frac{1}{x}$.Or do both.Also, when we say that the relationship is of $D(p) = Cp^{-\epsilon}$ (constant elasticity) type, we're essentially talking about above kind of relationship.		If it looks like this than transforming only the response variable to $\log y$ or $\frac{1}{y}$ is sufficient.
	If the relationship between x and y looks like this you use y^2, x^2 trasformation.								
	If it looks like this than transforming only the explanatory variable to $\log x$ or $\frac{1}{x}$ is sufficient.								
	Here, either we can transform: <ul style="list-style-type: none">y to $\log y$ or $\frac{1}{y}$ orx to $\log x$ or $\frac{1}{x}$.Or do both.Also, when we say that the relationship is of $D(p) = Cp^{-\epsilon}$ (constant elasticity) type, we're essentially talking about above kind of relationship.								
	If it looks like this than transforming only the response variable to $\log y$ or $\frac{1}{y}$ is sufficient.								
<div><ul style="list-style-type: none">After applying log-log transformation, what equation do we get?How do you compare this equation with SLR equation?And how do find C and ϵ from this equation?</div>	<div><div>Constant elasticity model</div><div><ul style="list-style-type: none">Log-log transformation can convert the relationship to a linear one. And we get:</div><div>$\text{Log}(D) = \text{Log}(C) - \epsilon \text{Log}(P).$</div></div>								

	<ul style="list-style-type: none">• An example of this is available in the Excel sheet.• $D(p) = Cp^{-\epsilon}$.• Take log on both sides we get$\log(D) = \log(C) - \epsilon \log(p)$<ul style="list-style-type: none">◦ Here, $\log(D) \rightarrow$ Response variable (y)◦ $\log(p) \rightarrow$ Explanatory variable (x)◦ and, we've transformed both variables. Now, this relationship looks like a linear relationship. Equivalent to SLR equation.$y = \beta_0 + \beta_1 x + \varepsilon$◦ $\beta_0 = \log(C) \rightarrow y$ -intercept or market-size◦ $\beta_1 = -\epsilon \rightarrow$ Slope• Now, we run SLR over this and get the estimate of β_0 and β_1.<ul style="list-style-type: none">◦ $\therefore C = \text{antilog}(\beta_0) = e^{\beta_0} = D(1) \rightarrow$ Demand when price = 1.◦ $\varepsilon = -\beta_1 \rightarrow$ Elasticity value.
